

## Abstract of the Disclosure

A container holder includes a member disposed in a closed position to be able to draw into an open position, a driving device attached to the member to move the member between the closed position and the open position, and a sensing device for sensing whether or not the member is drawn out for a predetermined amount from the closed position. A control device controls the driving device to cause the member to be housed when the sensing device senses that the member is not drawn out for a predetermined amount. Also, a container placed on a tray can be sensed assuredly regardless of vibration during a movement of a vehicle.
